ABSTRACT

Cisplatin is an organic metal co-ordination complex andis a widely used chemotherapeutic agent against a variety of malignant tumors, like sarcomas and carcinomas. It interferes with the DNA synthesis and causes apoptosis in view of the fact that the growth of normal cells is also affected. These toxic effects alter the metabolic function of certain tissues and organs. 60 albino rats weighing on an average 100 grams were taken. The animals were divided into three groups. Group A animals received no drug. Group B was injected with 1.3mg/m² of cisplatin by intraperitoneal route and group C received 2.5mg/m² of cisplatin. The process of drug administration was continued for 12 weeks. The animals were sacrificed in five sittings after interval of 1,3,6,9 and 12 weeks after drug administration. At the termination of experiments the testis were fixed and stained with H&E. There was degeneration of germ cells with increase in capsular wall thickness of testis, and leydig cell depletion and sertoli cell depletion in seminiferous tubules. All these findings were prominent in high dose group and progressively increased in severity. Besides this, there was loss of spermatozoa in the lumen of seminiferous tubules in both high and low dose group, but was profound in high dose group at 12th week. Though cisplatin effectively treats cancer, at an increased dose it has toxic effects to the genitourinary system and other parts of the body.

KEY WORDS: Cisplatin, Rat, Testis, Chemotherapeutic agent, Apoptosis, DNA synthesis

INTRODUCTION

Cisplatin was created by Michele Peyrone in 1844 and it was known as Peyrone’s Salt or Peyrone’s Chloride for a long time [1]. Cisplatin is a potent chemotherapeutic agent widely used for cancer treatment [2,3]. Cisplatin interferes with DNA replication, which kills the fastest proliferating cells, which in theory are carcinogenic [4,5]. The damaged DNA elicits DNA repair mechanisms, which causes cell cycle arrest in the G2-phase and then induces programmed cell death called as apoptosis [6]. Cisplatin is a cornerstone for the treatment of multiple cancers, including sarcomas, some carcinomas e.g. small cell cancer, squamous cell carcinoma of head and neck and ovarian cancer, lymphomas, bladder cancer, cervical cancer and germ cell tumors [2,3]. Cisplatin toxicities are common with higher doses which include Renal and neuropathic toxicities [7-10]. Cisplatin also seems to inhibit Leydig cell testosterone secretion [11] and usual changes in
hormonal levels observed during cisplatin treatment may be related to Leydig cell damage [12].

MATERIALS AND METHODS

The present randomised controlled trial (RCT) was conducted in the Postgraduate Department of Anatomy, Government Medical College Srinagar. Sixty male albino rats weighing on an average 100gms (0.1kg) were taken for the present study. The animals (rats) were obtained from animal house Govt medical college Srinagar. This study was conducted following the guidelines of the Animal Ethical committee, Government Medical College Srinagar. Animals were divided into three groups. Group A (control group) contain twenty (20) rats. These rats were fed normal diet which include grains, vegetables and tap water. Group B (low dose group) contain twenty (20) rats. This group was given low dose of cisplatin at the dose of 1.3mg/m². The drug was given intraperitoneally. The rats receive normal diet which includes grains, vegetables and tap water. Group C (high dose group) contain twenty rats (20). This group was given high dose of cisplatin at the dose of 2.5mg/m² intra peritoneally. The rats were sacrificed in five sittings at 1st week, 3rd week, 6th week, 9th week and 12th week. In each, sitting five rats were sacrificed from each group. After anaesthetizing with chloroform, midline abdominoperineal incision was given. Testes were identified, dissected and cleaned, and were put on blotting paper. The tissues were processed manually for block making and the slides were stained with haematoxyline and eosin under various steps. Then these prepared slides were seen under electronic microscope.

RESULTS AND DISCUSSION

Macroscopically there was no significant change at any week after drug administration.

PICTURES

Degeneration of Germ Cells in Seminiferous Tubules Treated with Cisplatin

Loss of Sperm Whorles in Lumen

Thickening of Capsular Wall of Testis Treated with Cisplatin

Microscopic changes:

Degeneration of germ cells in seminiferous tubules (T.DGS) There was no degeneration of germ cells in seminiferous tubules in control and low dose group at any week after drug administration, however high dose group showed mild change at 3rd and 6th week, moderate at 9th week and severe change at 12th week.

Capsular wall thickness of testes: There was no testicular capsular wall thickness in control and low dose group after cisplatin administration, however high dose group showed mild change at 3rd and 6th week, moderate at 9th and severe change at 12th week.
Sertoli cells in seminiferous tubules: There was no change in control group. However, 2 rats in low dose group showed mild decrease in Sertoli cells at 9th week and 2 rats in low dose group showed mild changes at 12th week and 2 rats showed moderate change at 12th week. In high dose group there was moderate change at 9th week in all rats and severe change at 12th week.

Spermatozoa in lumen: There was no change in control group, however low dose group showed mild decrease in spermatozoa at 12th week and high dose group showed mild decrease at 9th week and severe decrease in spermatozoa at 12th week.

In our study, there was no macroscopic change in the testis after administration of cisplatin, however histologically it was found that there was degeneration of germ cells in seminiferous tubules in high dose group, which started from 3rd week and gradually became severe till 12th week. Capsular wall thickness was prominent and began at 3rd week in high dose group and increased with time. There was leydigand sertoli cell depletion , which was more severe at 12th week in high dose group, however spermatozoa in lumen were severely affected only in high dose group at 12th week. Kadel M et al 2013 [13] while working on effects of cisplatin on testes and chromosomes of rats found similar results. It was found that there was significant reduction of germ cells and sertoli cells. High doses reveal severe atrophy and loss of normal architecture of seminiferous tubules, maturation arrest, cytoplasmic vacuolization and multinucleated giant cell formation.

Hejazi Sajjad 2012 [14] worked on Toxic effect of cisplatin treatment on rat testis tissues, and found similar results. In this study he choose 40 adult male Rats. The Rats were divided randomly into 2 groups as Control and Experimental. Rats of the experimental group were injected Cisplatin in 3 doses (20mg/m^2/5days- IP). The control group was injected by normal Saline. Microscopic study showed changes which included: diameter of seminiferous tubules and epithelial thickness and the average percentage of tubules with spermatozoa was significant diminished. Testicular atrophy with degeneration of germ cells in seminiferous tubules and testicular capsular wall thickness was prominent. The tubules were shrunken and greatly depleted of germ cells. There were depleted numbers of Leydig cells between the tubules. Sertoli cells with few germ cells were observed in the lumen.

CONCLUSION
Indubitably cisplatin is a cornerstone for the treatment of multiple cancers. However its significant antitumor action is often limited by the development of toxicity, which is evident in various animal species. When rats were treated with cisplatin, there was degeneration of germ cells in seminiferous tubules, with increase in capsular wall thickness of testis and leydig cell depletion and sertoli cell depletion. All these findings were prominent in high dose group and progressively increased in severity. Besides this, there was loss of spermatozoa in the lumen of seminiferous tubules in both high and low dose group, but was profound in high dose group at 12th week. This has clinical significance, as judicious monitoring of cisplatin is important. This would lead to better compliance and decrease the morbidity of the patients.

ACKNOWLEDGEMENTS
“Whole Praise is for Allah Who Has Guided Me from Darkness to Enlightenment, To Solace and Contentment” I express my gratitude
to my husband - Dr Ubaid Ali, my son Mohammad Mahir, Dr Martin Lucas, Dr Anisha, Dr Sangeetha, Dr Shaheen Shahdad, without whose help and guidance this study would not have been complete.
