INTERVENTIONS FOR INCREASING BALANCE & CONFIDENCE IN OLDER ADULTS: A REVIEW

Foram Dhebar.

Lecturer, Sigma Institute of Physiotherapy, Bakrol, Vadodara, Gujarat, India.

ABSTRACT

Elderly is defined as being 65 years of age or older. Geriatrics or geriatric medicine is a specialty that focuses on health care of elderly people. The number of persons above the age of 60 years is fast growing, especially in India. Falls are the leading cause of traumatic brain injury, fractures & the leading cause of emergency department visits by older adults. Low balance confidence is a major health problem among older adults restricting their participation in daily life. Objective of this review is to determine what interventions are most effective in increasing balance & confidence in older adults. The American Geriatrics Society (AGS) published clinical guidelines 2011 that recommended all adults aged 65 years and older be screened for falls. Prevention of the fall can be done by combination of exercise include Strengthening exercise, Balance & co-ordination exercise, Hydrotherapy and allied therapeutics such as tai chi and yoga.

KEYWORDS: Geriatric, Balance, co-ordination, Fall, Intervention.

INTRODUCTION

Elderly is defined as being 65 years of age or older. Geriatrics or geriatric medicine is a specialty that focuses on health care of elderly people. The term geriatrics comes from the Greek word geron meaning “old man”, and iatros meaning “healer”. Elderly can be classified in to three groups: 1. Young old: between 65 and 75 years of age 2. Middle old: between 75 and 85 years of age. 3. Old: older than 85 years.

DEMOGRAPHY OF AGING

The number of persons above the age of 60 years is fast growing, especially in India. India as the second most populous country in the world has 76.6 million people at or over the age of 60, constituting above 7.7% of total population.

Following factors contributed in demographic changes occurred in last century

· Advances in medicine
· Healthier lifestyles
· Improved access to health care
· A steady decline in death rate from infectious diseases throughout adult life
· Availability of information about health, diseases and treatment through conventional media and the internet.

EPIDEMIOLOGY OF FALL

Fall can be defined as an event that results in a person's inadvertently coming to rest on ground or lower level with or without loss of consciousness or injury. Falls are the public health epidemic of this decade. More than 30% of people aged 65 years or older and more than 50% of people aged 80 years or older have an
event of fall. The incidence of falls (History of a single fall in the last 6 months) was found to be 14%, in 10 states across India. Falls and fractures are more common in females (2:1). Falls due to intrinsic causes and recurrent falls are common in people > 70 years. Falls are the leading cause of traumatic brain injury, fractures. It is the leading cause of emergency department visits by older adults, and the number one cause of hospital admissions due to trauma.

**BALANCE CONTROL**

Balance is a complex automatic integration of several body systems as shown in figure

![Fig. 1: Important resources required for postural control. CNS= Central Nervous System.](image)

**AGE RELATED CHANGES**

With age and inactivity these unconscious processes may not integrate as well or as quickly, so in order to maintain their balance and avoid falling older people may have to give a greater proportion of their attention to keeping upright with concomitant fatiguing effort.

Age-related changes in connective tissue results in further reduction of flexibility, loss of tensile strength in the ligaments, and greater rigidity in the muscles and peripheral support structures of the joints of the lower limb.

Changes in gait pattern may also be associated with balance (Nasher, 1993). Older people tend to step with a wider base, spending increased time in the double leg support phase of walking and minimizing the time spent on one leg. There is, therefore, a decrease in stride length and trunk rotation, with the result that a more unbalanced or even shuffling gait may develop.

**RISK FACTORS AND SCREENING**

The American Geriatrics Society (AGS) published clinical guidelines in 2001, subsequently expanded and revised in 2011, that recommended all adults aged 65 years and older be screened for falls.

The AGS published a 2011 update of the guidelines. The guidelines still specify all older adults be screened annually for falls by a healthcare provider, but now have expanded to include screening for balance and mobility impairments.

The screen consists of (1) asking the older person if they have experienced a fall over the past year (yes or no), (2) asking if they are experiencing difficulty with walking or with their balance (yes or no), and/or (3) observing whether performance of walking and balance is compromised (yes or no) using the Timed Up and Go test or other balance assessment. If one or more of these screens are “positive” the individual should be referred for a comprehensive multifactorial fall-risk assessment.

1. Obtain relevant history, physical examination, cognitive, and functional assessment
2. Determine multifactorial falls risk:
   - History of falls
   - Medication review
   - Gait, balance, mobility assessment
Foram Dhebar. INTERVENTIONS FOR INCREASING BALANCE & CONFIDENCE IN OLDER ADULTS: A REVIEW.

• Visual acuity
• Other neurological impairments
• Muscle strength
• Heart rate and rhythm
• Postural hypotension
• Feet and footwear
• Environmental hazards

Several reliable and validated tools are available to assess balance and mobility across the continuum of function:
- Berg Balance Scale,
- Performance-Oriented Mobility Assessment
- Dynamic Gait Index
- Timed Up and Go.

Psychological factors can be more disabling and have a greater impact on function than the fall itself and should therefore be an important consideration in rehabilitation programmes. Assessment should identify fall-related psychological factors that impact on confidence, activity restriction and participation. An appropriate outcome measure should be used such as the Falls Efficacy Scale (FES), FES - International (FES-I) or the Short FES.

FALL MANAGEMENT:

EXERCISE DOSE:

Sherrington’s meta-analysis of 44 studies determined the minimum dose of exercise to effectively reduce the risk and rate of falls is 50 hours. The delivery of the dose of exercise was dependent on the trial, with trials achieving the 50 hours over a period of 3 months, 6 months or longer.

MODE OF EXERCISE:

A recent Cochrane systematic review examining exercise interventions to improve balance among older people reported exercise interventions that included:
(a) gait, balance, coordination and function training;
(b) strength training;
(c) three dimensional training e.g. dance, tai chi; and
(d) mixed training were beneficial in relation to balance outcomes.

The most effective programmes involved dynamic exercise programmes that ran three times weekly training for three months.

(a) strength training

Strength is a key element of fall prevention; however, strength training alone without a balance component is not an effective strategy to prevent falls.

A recent meta-analysis identified the key components of strength training that translate to improved balance and reduced falls risk including: (1) A focus on lower-extremity and postural muscles; (2) Minimal upper-extremity support; (3) Delivered at either a moderate or high intensity to achieve the desired results. A few strength training interventions have resulted in more injuries compared with balance training:
- Danilo Sales, Bocalini, April 2010 had concluded that moderate resistance training for 1 hour – 3 times a week in non-consecutive days for 24 weeks improves fitness and suppress the decline in BMD without tacking hormone replacement therapy and reduce fall risk. The exercises include leg press, leg extension, leg curl, shoulder and elbow exercises at 60-70% of 1 RM considered as moderate resistance training.
- M. Martin, S.T. James. Jan.2009(national osteoporosis foundation): A systemic review and meta-analysis were undertaken and concluded that high intensity resistance training affect bone mineral density and decline bone loss in post menopausal woman. Which suggest improve bone health & less complication of fall.

Back extension exercise encourage both strength and later mobility
- Stretching to improve flexibility should be part of exercise programme.
- Stretching of whole major upper limb and lower limb muscles group should be carried out.
- It should be carried out following warm period ballistic stertching should be avoided

(b) Balance and co-ordination exercise
- Static activities

Exercises that challenge the center of mass (eg, reaching while standing) while the feet remain fixed, and exercises that practice a narrow base.
of support (eg, tandem series, single-leg stance) have been included in effective interventions.\textsuperscript{23,24} For greater challenge, a sensory component can be included (standing on an unstable surface or standing with the eyes closed)

- **Dynamic activities**
Activities that challenge the center of mass while the feet are in motion are dynamic activities. Dynamic activities tend to be functional, and may include reaching, turning in a circle, standing, and stair-stepping.\textsuperscript{25,26}

- **Dynamic gait training** can be incorporated into progression of intervention using dance steps, circling, figure eights, directional changes on command, obstacle courses, and dual-task training.\textsuperscript{27-28}

(c) **Dual-task training**
Involves doing a primary task (maintaining postural control or walking speed) while performing a secondary task (eg, a cognitive challenge such as counting backwards, or a manual task such as carrying an item).\textsuperscript{29}

In a randomized controlled trial on the effects of single-task versus dual-task training on balance performance in older adults, Silsupadol et al found that changing the focus of the dual-task priority instructions from a priority on cognitive to a priority on the physical task resulted in greater improvements of performance.\textsuperscript{30}

(d) **To prevent the consequences of a long lie**
Up to half of non-injured fallers are unable to get up again\textsuperscript{31}. The inability to get up from the floor independently following a fall is associated with subsequent serious fall-related injury and increased mortality.\textsuperscript{32} The consequences of a long lie on the floor (> 1 hour) include pressure sores, hypothermia and dehydration and increased risk of admission to hospital with a subsequent fall, or moving into long term care.\textsuperscript{33}

There is some evidence that teaching and practicing how to get up from the floor is acceptable to older people and can be successful.\textsuperscript{34,35}

(e) **Small Group session for community elders**
A Matter of Balance includes eight two-hour sessions for a small group led by a trained facilitator. This nationally recognized program was developed at the Roybal Center at Boston University.

During the class, participants learn to:
- View falls as controllable
- Set goals for increasing activity
- Make changes to reduce fall risk at home
- Exercise to increase strength and balance

Participants experienced significant increases in Falls Efficacy, Falls Management, and Falls Control at six weeks, six months, and 12 months.\textsuperscript{36}

(f) **Hydrotherapy**
Hydrotherapy is used to treat rheumatic, orthopedic and neurological disorders. It has been the subject of investigations regarding balance recovery in elderly people. The situation is different with exercises in an aquatic environment, where there is a reduction in joint overload and less risk of falls and lesions. In addition, floating allows individuals to perform exercises and movements that cannot be done on the ground.\textsuperscript{37,38} Although few studies have reported the effects of hydrotherapy on balance and the reduction of falls, all of them have shown benefits. It includes following plan of care.

Phase I – Aquatic environment adaptation.
Phase II – Stretching. Each stretching exercise was maintained for 30 seconds.
Phase III – Static and dynamic exercises for balance.

(g) **Allied therapeutics:**
- **Tai Chi**
Several research studies assessing Tai Chi as an intervention to improve balance and prevent falls have reported favorable outcomes.\textsuperscript{39-40} However, it does appear that to be effective, the minimal dose must be achieved. Interventions that are less than 12 weeks typically are not as effective in improving balance and preventing falls as those of 12 weeks or greater.\textsuperscript{41-42}

- **Yoga**
Several authors have shown that including specific asana in an overall yoga program for older adults may improve balance\textsuperscript{43} and gait speed\textsuperscript{44} Yoga programs designed specifically for older adults should include a combination of sitting and standing asana and modifications such as warming up with heel raises and the use of a chair to reduce the fear of falling during the practice.
CONCLUSION
The research supports the most effective interventions to manage falls risk are those that incorporate exercise. For optimal results, the exercise program needs to be structured, progressed, and must achieve the minimum dose of exercise. Exercise include strength training, Balance and co-ordination exercise, Dual-task training. Hydrotherapy & Allied therapeutics: yoga & tai chi can also have beneficary effects.
